

Make AI measurable enough to scale - and usable enough to stay.

MANDATE	Build the enterprise deployment operating system: align priorities, qualify use cases, establish governance, carry pilots into adopted workflows, track value and leave sustainment ownership.
---------	--

OPERATING CONTRADICTIONS

Speed / control	Accelerate learning without bypassing quality, authority or risk.
Enterprise / local	Activate Danaher capability without forcing generic workflows onto SCIEX functions.
Portfolio / workflow	Maintain executive visibility without losing the user, baseline and process owner.
Go-live / adoption	Treat behavior change and user evidence as part of deployment.
Pilot / sustainment	Prevent orphaned tools through ownership, support and standard work.

AI DEPLOYMENT ASSAY

Signal	Business problem, decision, user, baseline and outcome.
Method	Workflow insertion, data path, platform, integration and test.
Control	Human authority, risk boundary, exception and escalation.
Response	Outcome evidence, retained use, quality and value.
Transfer	Owner, standard work, support, learning and sustainment.

THE HARD OBJECTION

No direct mass-spectrometry or diagnostics-company career.

Own it. Do not claim domain equivalence. Offer adjacent evidence and a bounded, expert-owned proof.

PROOF STRATEGY

- 01** Select one workflow where SCIEX experts retain decision authority.
- 02** Establish a trusted baseline, risk boundary, user and outcome owner.
- 03** Run the AI Deployment Assay with DBS operating cadence.
- 04** Review outcome, adoption, quality and support evidence.
- 05** Standardize only if the mechanism holds; stop or redesign when it does not.

EVIDENCE TO FOREGROUND

Vape-Jet	Current AI-first operating transformation across production, quality, support, ERP, CRM, issue flow and telemetry.
DudeWorth	Use-case qualification, agentic workflow design, human authority, evaluation and governance.
Amazon	Launch discipline, Gemba, standard work, escalation and scaled operating cadence.
Compunetics	High-reliability engineering/manufacturing, quality systems and technical-customer translation.
ZeusVu	Regulated autonomous operations, safety discipline and governed field deployment.

- 01 **What would make this role an undeniable success twelve months from now - a portfolio outcome, a handful of scaled workflows, an operating model, or all three?**
- 02 Where does AI demand currently enter SCIEX, and where does it most often stall: prioritization, data, integration, ownership, change readiness or sustainment?
- 03 **How should the AI Steering Committee divide decision rights among business leaders, IT, DBS, quality/regulatory and Danaher platform owners?**
- 04 Which Danaher AI investments are ready to activate at SCIEX, and which still require local workflow design or evidence?
- 05 **Where would you place the first two lighthouse deployments across service, commercial, operations or quality - and why?**
- 06 What measures are already trusted for value realization, and where are baselines or ownership still weak?
- 07 How much standardization is desirable globally, and where must regional or functional variation remain legitimate?
- 08 **What is the most plausible reason a technically successful pilot would fail to become daily work here?**
- 09 Which risks need hard gates, and which should be managed through rapid learning and review-by-exception?
- 10 When the initial portfolio proves value, what team capability should this leader build first?

I would not ask SCIEX to trust a generic AI transformation promise. I would ask for a bounded workflow, expert authority, a clear baseline and the opportunity to prove a disciplined deployment mechanism.
